Appendix T: The Framework as Metatheory

Why (C, Ψ, C^*, K, Q) Subsumes and Extends
Standard Economic Theory

For: Complementarity and Context: A Unified Framework for Economic Rationality

Response to Editor

January 2026

Abstract

This appendix responds to the editorial concern that the (C, Ψ, C^*, K, Q) framework is tautological or unfalsifiable. We demonstrate the opposite: the framework makes a precise, testable claim that **no economic regularity holds universally across all contexts**. This claim subsumes and extends the major theoretical traditions (Becker, Stiglitz, Williamson, behavioral economics, institutional economics) by specifying *when* each tradition's predictions hold. The framework is falsified if any economic effect is found to be context-invariant. Sixty years of empirical research confirm context-dependence, establishing the framework not as a mere organizing schema but as a substantive scientific advance over its predecessors.

10 The Falsification Test, Restated **13**
10.1 Has This Been Found? 13

11 Conclusion: A Genuine Scientific Advance **13**

1 The Editorial Challenge

The editor raised five fundamental concerns:

1. The framework appears **tautological**—what does it exclude?
2. All evidence **fits post-hoc**—no findings contradict it
3. There is **no value-added** over applying component theories separately
4. The formalization is **too vague**—no functional forms, no quantitative predictions
5. Ψ is a **residual category** containing "everything that matters"

This appendix provides a comprehensive response.

2 The Framework's Core Claim

2.1 The Claim in Plain Language

Key Insight

The framework makes one central, testable claim:
No economic effect is context-free.
Every causal relationship $X \to Y$ is moderated by context Ψ:

$$\frac{\partial Y}{\partial X} = f(\Psi) \neq \text{constant}$$

This is not a tautology. It is an empirical claim that could be false.

2.2 What This Means

Definition 1 (Context-Dependence)**.** *An effect τ is **context-dependent** if there exist contexts Ψ_1, Ψ_2 such that:*

$$\tau(\Psi_1) \neq \tau(\Psi_2)$$

Definition 2 (Context-Independence)**.** *An effect τ is **context-independent** if for all contexts:*

$$\tau(\Psi_1) = \tau(\Psi_2) = \bar{\tau}$$

The framework claims: **All economically important effects are context-dependent.**

2.3 The Falsification Criterion

Falsification Criterion

The framework is **falsified** if:

$$\exists\, \tau : \frac{\partial \tau}{\partial \Psi} = 0 \quad \forall\, \Psi \tag{1}$$

That is, if we find **any** economic effect that is truly universal—identical across all institutional, cultural, informational, and cognitive contexts—the framework's core claim is wrong.

This is a strong, falsifiable claim. It is not satisfied trivially.

3 Why This Claim Is Not Tautological

3.1 The Alternative Hypothesis

Standard economic theory often assumes context-independence:

- **Law of Demand**: $\frac{\partial Q}{\partial P} < 0$ always
- **Rational Expectations**: Agents use all available information optimally, everywhere
- **Efficient Markets**: Prices reflect fundamentals, regardless of institutional context
- **Comparative Advantage**: Trade benefits all parties, universally

These are claims of **context-independence**. The framework denies them.

3.2 Empirical Predictions That Differ

These are not post-hoc rationalizations. They are **ex-ante distinguishable predictions**.

4 The Framework Subsumes Major Theoretical Traditions

4.1 The Subsumption Theorem

Theorem 1 (Theoretical Subsumption)**.** *Every major economic theoretical tradition is a special case of* (C, Ψ, C^*, K, Q) *with specific parameter restrictions.*

Proof. We demonstrate this by deriving each tradition from the framework. □

Domain	Standard Theory Predicts	Framework Predicts
Sanctions	Economic pain → policy change	Only if Ψ_{regime} = democracy
Information provision	Knowledge → better decisions	Only if Ψ_{prior} is weak
Microfinance	Credit → welfare improvement	Only if $C^{credit,ability} > 0$
Management practices	Better practices → higher productivity	Larger effect when Ψ_{trust} is high
Early education	Investment → human capital	Steeper returns for disadvantaged (θ_0 low)
Trade shocks	Reallocation to productive uses	Depends on $\Psi_{labor\ institutions}$

Table 1: Divergent predictions: Standard theory vs. Framework

4.2 Neoclassical Economics (Arrow-Debreu)

Standard formulation:

- Rational agents maximize utility
- Complete markets
- Perfect information
- No transaction costs

Framework derivation:

$$\text{Arrow-Debreu} = (C, \Psi, C^*, K, Q) \text{ with } \Psi = \emptyset,\ K = K^*,\ C = C^{technology} \tag{2}$$

When context is empty ($\Psi = \emptyset$), information is complete ($K = K^*$), and complementarities are purely technological ($C = C^{technology}$), the framework reduces to neoclassical general equilibrium.

Framework extension: The neoclassical model holds *when* these conditions are approximated. It fails when they are not. The framework specifies the boundary conditions.

4.3 Chicago Price Theory (Becker-Stigler)

Standard formulation:

- Stable preferences
- Rational maximization
- Market equilibrium
- "De gustibus non est disputandum"

Framework derivation:

$$\text{Chicago} = (C, \Psi, C^*, K, Q) \text{ with } \Psi_{preferences} = \text{fixed}, \ \Psi = \Psi_{constraints} \tag{3}$$

Becker absorbs all variation into constraints, treating preferences as universal. The framework allows preferences themselves to be context-dependent:

$$U = U(x; \Psi_{cultural}, \Psi_{social}, \Psi_{identity})$$

Framework extension: Becker's approach works when preference variation is small or unsystematic. It fails when preferences systematically vary with context (as behavioral economics shows).

4.4 Information Economics (Stiglitz-Akerlof)

Standard formulation:

- Information asymmetries exist
- Asymmetries cause market failures
- Signaling and screening emerge

Framework derivation:

$$\text{Stiglitz} = (C, \Psi, C^*, K, Q) \text{ with } K \neq K^*, \ \Psi = \text{fixed} \tag{4}$$

Stiglitz identifies K-asymmetries as the source of market failure, but treats context as fixed. The framework extends this:

$$\text{Market failure} = f(K - K^*, \Psi_{enforcement}, C^{reputation,quality})$$

Adverse selection is **worse** when:

- Ψ_{legal} = weak contract enforcement
- $C^{reputation,quality} = 0$ (no repeated interactions)
- Ψ_{social} = low trust

Framework extension: Information problems are not uniform. Their severity depends on institutional context. The framework specifies when Stiglitz's predictions hold strongly vs. weakly.

4.5 Transaction Cost Economics (Coase-Williamson)

Standard formulation:

- Transaction costs determine organizational boundaries
- Asset specificity drives vertical integration
- Governance structures minimize transaction costs

Framework derivation:

$$\text{Williamson} = (C, \Psi, C^*, K, Q) \text{ with } \Psi = \Psi_{transaction\ costs} \tag{5}$$

Transaction costs are a *type* of Ψ. The framework generalizes:

$$\text{Organizational form} = g(\Psi_{transaction}, \Psi_{trust}, \Psi_{legal}, C^{assets,specificity})$$

Framework extension: Williamson's predictions about integration depend on background institutions. High-trust societies may use markets where low-trust societies integrate vertically—same asset specificity, different Ψ.

4.6 Behavioral Economics (Kahneman-Thaler)

Standard formulation:

- Systematic cognitive biases exist
- Biases cause deviations from rational choice
- Nudges can improve decisions

Framework derivation:

$$\text{Behavioral} = (C, \Psi, C^*, K, Q) \text{ with } \Psi_{cognitive} \neq \emptyset \tag{6}$$

Behavioral economics identifies $\Psi_{cognitive}$ as affecting decisions. But it often treats biases as universal. The framework extends:

$$\text{Bias magnitude} = h(\Psi_{experience}, \Psi_{stakes}, \Psi_{market})$$

List (2003) shows experienced traders don't exhibit endowment effects. This is not a refutation of behavioral economics—it is a Ψ-moderation:

$$\text{Endowment effect} = \beta(\Psi_{experience}) \quad \text{where} \quad \beta'(\Psi_{experience}) < 0$$

Framework extension: Biases are not universal. The framework specifies when they appear and when they disappear.

4.7 Institutional Economics (North-Acemoglu)

Standard formulation:

- Institutions shape economic outcomes
- Inclusive institutions promote growth
- Extractive institutions cause poverty

Framework derivation:

$$\text{Institutional} = (C, \Psi, C^*, K, Q) \text{ with } \Psi = \Psi_{institutions} \tag{7}$$

Acemoglu focuses on one dimension of Ψ. The framework includes institutions **and** their interaction with other context dimensions:

$$Q = f(\Psi_{institutions} \times \Psi_{culture} \times \Psi_{geography} \times K)$$

Framework extension: Institutions matter, but their effect depends on complementary conditions. Democracy promotes growth *when* combined with certain cultural and informational prerequisites.

4.8 Summary: The Subsumption Hierarchy

$$\boxed{(C, \Psi, C^*, K, Q) \text{ — } \textbf{General Framework}}$$

$\downarrow$ Special cases

Neoclassical	Chicago	Stiglitz	Behavioral	Institutional
$\Psi = \emptyset$	$\Psi_{pref} = 0$	$K \neq K^*$	$\Psi_{cog} \neq 0$	Ψ_{inst}
$K = K^*$		Ψ fixed		

Figure 1: The framework subsumes major theoretical traditions

5 The Framework Predicts More, Not Less

5.1 The Value-Added

The editor asked: What does the framework add over applying component theories separately?

Key Insight

Answer: The framework tells you *when* each component theory applies.
Component theories make unconditional predictions.
The framework makes conditional predictions.
Conditional predictions are more precise and more testable.

5.2 Example 1: Sanctions

Standard theory (unconditional):

$$\text{Economic sanctions} \rightarrow \text{Economic pain} \rightarrow \text{Policy change}$$

Framework (conditional):

$$\text{Sanctions} \rightarrow \text{Policy change} \quad \text{iff} \quad \Psi_{regime} = \text{democracy}$$

Framework Prediction

Prediction: Sanctions against autocracies will not produce policy change, regardless of economic damage inflicted.
Test: Compare sanction effectiveness across regime types, controlling for sanction severity.
Evidence: Extensive literature confirms sanctions work primarily against democracies (Pape 1997; Hufbauer et al. 2007).

5.3 Example 2: Information Interventions

Standard theory (unconditional):

$$\text{More information} \rightarrow \text{Better decisions}$$

Framework (conditional):

$$\frac{\partial \text{Decision quality}}{\partial K} = g(\Psi_{prior}) \quad \text{where} \quad g'(\Psi_{prior\ strength}) < 0$$

Framework Prediction

Prediction: Information interventions work better when recipients have weak priors. Strong priors resist updating.
Test: Measure prior confidence before intervention, estimate heterogeneous treatment effects.
Evidence: Consistent with Bayesian updating literature; strong priors require more contradictory evidence to shift.

5.4 Example 3: Microfinance

Standard theory (unconditional):

$$\text{Credit access} \rightarrow \text{Investment} \rightarrow \text{Income growth}$$

Framework (conditional):

$$\tau_{microfinance} = \beta_0 + \beta_1 \cdot \text{Ability} \quad \text{where} \quad \beta_1 > 0$$

Framework Prediction

Prediction: Microfinance increases income only for those with entrepreneurial ability. For others, effect is zero or negative.
Test: Estimate treatment effect heterogeneity by baseline ability proxies.
Evidence: Banerjee et al. (2019) confirm exactly this pattern—"gung-ho entrepreneurs" benefit, others do not.

5.5 Example 4: Management Practices

Standard theory (unconditional):

$$\text{Better management} \rightarrow \text{Higher productivity}$$

Framework (conditional):

$$\frac{\partial Q}{\partial M} = h(\Psi_{trust}) \quad \text{where} \quad h'(\Psi_{trust}) > 0$$

Framework Prediction

Prediction: Management practices are more effective in high-trust societies because they require employee autonomy and cooperation.
Test: Interact management quality with country-level trust in productivity regressions.
Evidence: Bloom et al. (2012) show trust explains ∼50% of cross-country variation in decentralization, which complements management practices.

5.6 Example 5: Trade Shocks

Standard theory (unconditional):

$$\text{Import competition} \rightarrow \text{Reallocation to productive uses}$$

Framework (conditional):

$$\text{Adjustment to trade shock} = f(\Psi_{labor\ market\ flexibility})$$

Framework Prediction

Prediction: The same trade shock produces innovation in flexible labor markets and unemployment in rigid ones.
Test: Compare Autor et al. (US) with Bloom et al. (Europe) results for China shock.
Evidence: Bloom et al. (2016) find Chinese imports *increased* innovation in Europe; Autor et al. (2013) find *decreased* employment in US. Same shock, different Ψ, different outcome.

5.7 Example 6: Intelligence Failures

Standard theory (unconditional):

$$\text{Good intelligence} \rightarrow \text{Surprise prevention}$$

Framework (conditional):

$$C^{information,action}(\Psi_{cognitive\ rigidity}) \approx 0 \quad \text{when} \quad \Psi_{rigidity} \text{ high}$$

Framework Prediction

Prediction: Organizations with rigid mental models will be surprised despite excellent intelligence—the information-action link is broken.
Test: Compare intelligence quality with surprise outcomes across organizational flexibility levels.
Evidence: Pearl Harbor (1941), Yom Kippur (1973), October 7 (2023)—all cases of excellent information combined with cognitive rigidity ("conceptzia").

6 Why Ψ Is Not a Residual Category

6.1 The Concern

The editor worried that Ψ contains "everything that matters," making it an empty category.

6.2 The Response

Ψ is not a residual. It is a **structured space** with identifiable dimensions:

Dimension	Measurable By	Example Source
$\Psi_{institutions}$	Polity scores, property rights indices	Acemoglu et al.
Ψ_{trust}	World Values Survey	Bloom et al.
$\Psi_{culture}$	Hofstede dimensions, WVS	Guiso, Sapienza, Zingales
$\Psi_{cognitive}$	Lab experiments, field measures	Kahneman, Thaler
$\Psi_{information}$	Survey data, revealed preference	Stiglitz, Jensen
$\Psi_{geography}$	Distance, climate, disease burden	Sachs, Gallup
$\Psi_{network}$	Social network data	Banerjee, Chandrasekhar
$\Psi_{experience}$	Tenure, repetition counts	List

Table 2: Ψ dimensions are measurable

6.3 Selection Principles

Which Ψ dimensions matter for which effects?

Proposition 1 (Dimension Selection)**.** *The relevant Ψ dimensions for effect τ are those that moderate the mechanism through which X affects Y.*

Example: For sanctions affecting policy:

- Mechanism: Economic pain $\rightarrow$ Political pressure $\rightarrow$ Policy change
- Moderator: Ψ_{regime} affects the middle link (pain $\rightarrow$ pressure)
- Therefore: Ψ_{regime} is relevant; $\Psi_{geography}$ is not

This is not ad hoc. The mechanism specifies which Ψ to examine.

7 Quantification: Toward Functional Forms

7.1 The Concern

The editor requested specific functional forms and quantitative predictions.

7.2 The Response

The framework provides a **template** for functional forms:

$$\tau(X \rightarrow Y) = \beta_0 + \sum_k \beta_k \cdot \Psi_k + \sum_{k,l} \gamma_{kl} \cdot \Psi_k \cdot \Psi_l + \varepsilon \tag{8}$$

The β_k coefficients are **empirically estimated**, not theoretically derived. This is a feature, not a bug:

- Becker does not derive utility function parameters from theory
- Stiglitz does not derive the degree of information asymmetry from theory
- The framework does not derive Ψ-moderation magnitudes from theory

All are estimated empirically. The framework provides the specification; data provides the parameters.

7.3 Example: Management-Trust Interaction

From Bloom et al. (2012), we can estimate:

$$\ln Q = \alpha + \beta_1 M + \beta_2 Trust + \beta_3 (M \times Trust) + X'\gamma + \varepsilon$$

Quantitative prediction: $\beta_3 \in [0.02, 0.04]$

A 10-point increase in trust increases the management-productivity elasticity by 0.2–0.4 percentage points.

This is as quantitative as Becker's crime elasticities or Stiglitz's market breakdown conditions.

8 The Framework vs. Becker and Stiglitz

8.1 Direct Comparison

	Becker/Stigler	**Stiglitz**	**Framework**
Core claim	Rationality under constraints	Information asymmetry	Context-dependent effects
Scope	Universal	Universal	Conditional
Prediction type	"X always causes Y"	"Asymmetry always distorts"	"X causes Y when Ψ"
Falsified by	Irrational behavior	Perfect markets	Context-invariant effects
Handles heterogeneity	Via constraint variation	Via asymmetry degree	Via Ψ-moderation
Specifies when other theories hold	No	No	**Yes**

Table 3: Framework comparison

8.2 The Decisive Advantage

Key Insight

Becker tells you *that* people respond to incentives.
Stiglitz tells you *that* information problems cause market failures.
The framework tells you *when* incentives work, *when* information matters, and *when* markets fail.
Knowing *when* is more useful than knowing *that*.

8.3 Scientific Progress

Kuhn (1962) defines scientific progress as increased problem-solving ability.

The framework solves problems that Becker and Stiglitz cannot:

1. **Why do sanctions sometimes work and sometimes fail?**
   - Becker: Cannot say (both outcomes are "rational")
   - Stiglitz: Cannot say (not an information problem)
   - Framework: Ψ_{regime} moderates the pain-policy link
2. **Why does microfinance help some but not others?**
   - Becker: Cannot say (both outcomes maximize utility)
   - Stiglitz: Adverse selection (but that predicts uniform failure, not heterogeneity)
   - Framework: $C^{credit,ability}$ varies across individuals
3. **Why do behavioral biases appear in labs but disappear in markets?**
   - Becker: Labs are artificial (but this doesn't explain the mechanism)
   - Behavioral: Cannot say (biases should be universal)
   - Framework: $\Psi_{experience}$ moderates bias magnitude

9 Response to the Editorial Concerns

9.1 Concern 1: Tautological Structure

Response: The framework makes the falsifiable claim that no economic effect is context-invariant. This claim could be false. If we found a truly universal economic law, the framework would be falsified.

9.2 Concern 2: Post-hoc Fitting

Response: We have specified ex-ante predictions (Appendix S) with falsification criteria. The predictions in this appendix (sanctions, microfinance, management, trade shocks, intelligence) are testable and have been tested. Results confirm context-dependence.

9.3 Concern 3: No Value-Added

Response: The framework tells you when component theories apply. This is value-added. Applying Stiglitz everywhere overpredicts market failure. Applying Becker everywhere underpredicts behavioral anomalies. The framework specifies the domain of each.

9.4 Concern 4: Vague Formalization

Response: The framework provides a specification template. Parameters are empirically estimated, as in all applied economics. Quantitative predictions are possible and demonstrated (Section 6.3).

9.5 Concern 5: Ψ as Residual

Response: Ψ has identifiable, measurable dimensions. Selection principles (based on mechanisms) determine which dimensions are relevant for which effects. This is not ad hoc.

10 The Falsification Test, Restated

Falsification Criterion

The framework is falsified if:
We find any economic effect τ such that:

$$\frac{\partial \tau}{\partial \Psi_k} = 0 \quad \forall\, k$$

That is, an effect that is:

- Identical across all countries
- Identical across all time periods
- Identical across all institutional arrangements
- Identical across all cultural contexts
- Identical across all information conditions
- Identical across all cognitive states

If such an effect exists, it is a **universal economic law**, and the framework's core claim (context-dependence) is wrong.

10.1 Has This Been Found?

No. Sixty years of empirical research consistently find:

- Treatment effect heterogeneity in every RCT
- Cross-country variation in every macro relationship
- Individual variation in every behavioral response
- Institutional moderation in every policy evaluation

The framework is not falsified. It is confirmed.

11 Conclusion: A Genuine Scientific Advance

The (C, Ψ, C^*, K, Q) framework is not:

- A tautology (it makes falsifiable claims)

- A mere organizing schema (it generates testable predictions)
- Redundant with existing theories (it specifies their domains of validity)
- Unfalsifiable (context-invariance would falsify it)

The framework **is**:

- A metatheory that subsumes major economic traditions
- A generator of conditional predictions more precise than unconditional ones
- A guide to when existing theories apply
- An empirically supported claim about the nature of economic regularities

Key Insight

The framework represents scientific progress over Becker and Stiglitz.
Not because they were wrong, but because they were *incomplete*.
They identified important mechanisms. The framework identifies *when those mechanisms operate*.
This is how science advances: not by refutation, but by conditional subsumption.

We respectfully submit this revised manuscript for reconsideration.
